NO.8

AUGUST, 1990

Acknowledgments

This paper is prepared under the Macroeconomic and Industrial Policy Research Programme at the NIPFP. An earlier version of the paper was presented at a Round Table discussion on "Issues Relating to Industrial and Trade Liberalisation and Export Growth" organised by the NIPFP on January 23, 1990 and at a Seminar on "International Trade and Development : Implications of Recent Theoretical Research and Experience", organised by the International Trade and Development Division, School of International Studies, Jawaharlal Nehru University, New Delhi, on February 8-10, 1990. We have benefited greatly from the comments of Prof. M. Datta-Chaudhuri, Prof. K.L. Krishna, Dr. Narhari Rao, and other participants at the Round Table and the Seminar. We are also grateful to an anonymous referee for many helpful comments and suggestions.

Abstract

The import policy for capital goods has been increasingly liberalised since the mid-1970s. The analysis presented in this paper indicates that a significant effect of the import policy liberalisation occurred only in the early 1980s. The analysis also brings out that the recent increases in capital goods imports are largely attributable to the depreciation of the Indian Rupee, and the contribution of the 1985 import policy changes was small. Regarding the effect of import liberalisation on the financial performance of the Indian capital goods manufacturers, the study comes to the conclusion that the domestic industry taken as a whole was not seriously affected by the liberalisation of import policy; at least the effect was not as alarming as is often made out.

Liberalisation of Capital Goods Imports in India

Introduction

A major achievement of our inward-looking industrialisation strategy is that India has now a large and well-diversified capital goods sector, which has enabled the country to attain a high degree of self-sufficiency in capital goods. While at the beginning of the planning era we had to depend on foreign producers for more than three-fourths of our requirements of capital goods (machinery and equipment), by the mid-1970s, indigenous production constituted about 85 per cent of the domestic availability of capital goods.

However, from 1976-77 began a gradual process of liberalisation of imports of capital goods into India. Two recent studies (Chandrasekhar 1987, and Singh and Ghosh 1988) have examined this phase of development of India's capital goods sector and come to the conclusion that the liberalisation of capital goods imports had a significant adverse effect on the domestic industry. In these studies, data have been presented to show that the share of imports in domestic availability of machinery and equipment has been on the rise since the mid-1970s. Empirical evidence has also been presented to indicate that increasing competition from abroad has adversely affected growth, production, capacity utilisation, employment and financial performance of domestic capital goods producers.

In both studies, serious concern has been expressed over the 1985 import policy, which has further liberalised imports of capital goods. Singh and Ghosh (1988) seem to hold the view that the consequences of the March 1985 import liberalisation measures would be disastrous for the domestic capital goods industry. Similar views have been expressed in several other articles published in the last four years.

The issue under discussion being a very important one, there is need for more empirical studies on it. In this paper, we examine empirically certain aspects of the liberalisation of capital goods imports in India.

Growth of Capital Goods Imports in the 1980s

India's imports of capital goods (machinery and transport equipment) for the period 1980-81 to 1988-89 are shown in Table 1. It is seen from the table that between 1980-81 and 1984-85, the value of imports of machinery and transport equipment increased from Rs.1821 crores to Rs.3027 crores, marking a growth rate of 13.5 per cent per annum. In the next two years, the value of imports more than doubled, from about Rs.3 thousand crores to over Rs.6 thousand crores. Expressed in U.S. dollars, the increase in the value of imports of capital goods was from \$2546 million to \$4914 million, again a rise by about 100 per cent. Between 1984-85 and 1988-89, capital goods imports increased at the rate of 22.2 per cent per annum, which was well above the growth rate of 13.5 per cent per annum recorded during the period 1980-81 to 1984-85. Expressed in U.S. dollars, the value of capital goods imports marked a growth rate of 16.3 per cent per annum between 1984-85 and 1988-89, far exceeding the growth rate of 2.5 per cent per annum between 1980-81 and 1984-85.

The figures on capital goods imports presented in Table 1 indicate that, in the two years following the import policy changes made in March 1985, there was a sharp rise in imports of capital goods. One would be tempted to treat this as a direct consequence of the liberalisation of import policy for capital goods. A closer examination reveals, however, that a large part of the observed increase in the value of capital goods imports was caused by the depreciation of the Indian Rupee vis-a-vis other currencies. This is brought out by Table 2. To make adjustments for exchange rate variations, a weighted average of the exchange rates of Indian Rupee vis-a-vis Dollar (U.S.), Pound (U.K.), Franc (France), Deutsche Mark (FRG), Yen (Japan) and Won (Korea) is taken, using as weights the relative shares of these six countries in India's

imports of machinery and transport equipment (in 1984-85). Table 2 shows the index of import value of machinery and transport equipment (base 1984-85 = 100). It is interesting to note from the table that while between 1984-85 and 1986-87, imports of capital goods expressed in Indian Rupee increased by 107 per cent, the increase was only by 60 when import values are expressed in sdr, and 46 per cent when a weighted average of exchange rates are used. It is also seen that in the last case, there was a significant fall in the value of imports between 1986-87 and 1988-89. Indeed, looking at index shown at the last column of the table, it would be realised that the growth rate of the value of capital goods imports (corrected for exchange rate variations) was much smaller (4.85% per annum) in the period 1984-85 to 1988-89 than in the period 1980-81 to 1984-85 (11.06% per annum).

Expansion of OGL List for Capital Goods

In Import Policy for 1985-88, 201 items of capital goods were added to the OGL (Open General Licence) list. Several authors, writing on import policy changes made in 1985, have considered this a significant liberalisation of capital goods imports. Since there was a sharp increase in the value of capital goods imports between 1984-85 and 1986-87, it would be interesting to find out whether this act of placing a large number of capital goods items under OGL was an important cause for the increase in import value.

To answer this question, one should compare the value of imports of the capital goods items newly added to the OGL list during the period 1984-85 to 1986-87. This, however, we could not do, as data on imports were not available at sufficiently disaggregate level to make it possible to get the value of imports of the individual items of the OGL list. We therefore took an indirect approach and estimated for 1986-87 the total value of imports of all the items in the OGL list, drawing data from Statistics of India's Foreign Trade (DGCI&S, Ministry of Commerce). This proved to be a very difficult task. The method that we followed to estimate the value of imports of capital goods under OGL is briefly described below.

The OGL list included about 1000 items. For about 150 items, we could clearly identify the RITC categories at 7-digit level. This group of items is hereafter referred to as OGL group I. For about 120 items, we could find the RITC 7-digit categories, but the items included in the OGL list did not match exactly with the RITC categories. The problem was more serious for 7 items among these 120, for which it was found that the item(s) listed under OGL constituted only a part of the identified RITC category. For these 7 items, half of the reported import value for the relevant RITC category was taken as import under OGL. This group of items is hereafter referred to as OGL group II. For about 100 items, the value of imports was not reported in the data sources mentioned above, presumably because imports of such items were nil or negligible. The remaining items about 630 in all belonged mostly to "others" and "not elsewhere specified" categories of various product groups in the RITC classification. These RITC categories included many items besides the one(s) in the OGL list, so that the value of imports under OGL probably formed only a small part of the reported figures on imports. An examination of the OGL list revealed that about 300, among these remaining 630 items, were concentrated in 7 RITC categories at 7-digit level. Though, for these RITC categories, the value of imports under OGL is expected to form only a small part of the reported figure on imports, the actual proportion could not be estimated. Thus, we proceeded with the assumption that OGL imports constituted 10 per cent of the reported import value¹. This group of items is hereafter referred to as OGL group III. We obtained our estimate of the value of capital goods imports under OGL by summing the reported import values for items belonging to OGL groups I and II (with 50% adjustment in respect of 7 items of the latter group), and adding to it 10 per cent of the reported figures on imports for the RITC categories to which the items of OGL group III belonged.

According to our estimate, the value of capital goods imports under OGL was Rs.473 crores in 1986-87. The total value of imports of capital goods² (defined broadly to include professional and scientific apparatus and equipment [RITC 87] and photographic and cinematographic equipment [RITC 88] along with machinery and transport equipment [RITC 7]) was Rs. 6792 crores in

that year. Thus, the estimated value of capital goods imports under OGL is found to constitute about 7 per cent of the total value of capital goods imports in 1986-87.

It is important to recognise here two limitations of the estimate of the value of capital goods imports under OGL, presented above. First, since exact matching could not be done between the OGL list and the RITC categories, some ad hoc ratios had to be applied to compute the imports under OGL. This has made the estimate crucially dependent on the ratios chosen. If, for OGL group III, the ratio is taken as 25% in place of 10%, then the estimate of capital goods imports under OGL for 1986-87 turns out to be Rs.686 crores, constituting about 10 per cent of the total value of capital goods imports for that year. Secondly, in our computation we have not included about 300 items out of the total of about 1000 items under OGL. This has caused an underestimation of the value of capital goods imports under OGL, the extent of which is difficult to ascertain.

Clearly, there may be a significant margin of error in our estimate of the value of capital goods imports under OGL. It seems to us, however, that the true proportion of capital goods imports under OGL would not be much higher than what our computations indicate. Accordingly, it may be inferred that the share of the 201 new items of the OGL list was small, probably very small, so that their placement under OGL did not contribute much to the growth of capital goods imports between 1984-85 and 1986-87³.

Share of Imported Capital Goods

Both Chandrasekhar (1987) and Singh and Ghosh (1988) have noted in their papers that the share of imports in domestic availability of machinery and equipment increased significantly over the period 1976-77 to 1983-84. For computing the relevant ratio, they have used data on production, imports and exports of machinery and transport equipment at current prices. Since current price data have been used, the computed ratio is affected by variations in price and exchange rate, and it may not therefore correctly show

inter-temporal changes in the extent of import penetration in the capital goods sector. Keeping this in view, we have used for our analysis a deflated series on imports of machinery and transport equipment. Deflation has been done by the unit value index⁴ of imports of machinery and transport equipment. Also, we have used a different ratio than the one used by Chandrasekhar, and Singh and Ghosh, namely, the ratio of real imports of capital goods to real domestic gross fixed capital formation in machinery and equipment⁵.

Table 3 shows for the period 1968-69 to 1986-87 the ratio of real imports of capital goods to real gross domestic fixed capital formation in machinery and equipment (both at 1970-71 prices). A graphic presentation is made in Chart 1. From Table 3 (and the Chart) one can clearly observe a downward trend in the ratio in the period 1968-69 to 1975-76. It is interesting to note that the downward trend continued beyond the mid-1970s (despite liberalisation of import policy for capital goods), up to 1979-80. It is in the 1980s that the ratio started rising. It reached a peak in 1983-84, and then declined sharply in the following year. The ratio increased again in 1985-86 and 1986-87, but the relative share of imported capital goods remained lower than that in 1983-84. Some rough estimates made for recent years indicate that in 1988-89 the ratio was lower than its 1986-87 level (note, in Table 2, the decline in the value of capital goods imports in 1987-88 and 1988-89).

Since, for analysing import penetration, we have used the ratio of imports to domestic investment, while Chandrasekhar, and Singh and Ghosh have used the ratio of imports to availability (production minus exports plus imports), our results are not strictly comparable to theirs. Also, the trends observed in the degree of import penetration may be peculiar to the ratio chosen for the study. These considerations have led us to compute also the conventional import-availability ratios, which are shown in Table 4.

Import-availability ratios have been computed for the years 1975-76 to 1985-86, at both current and constant prices. Data on domestic production have been drawn from Annual Survey of Industries (ASI). Data on imports and

exports have been drawn from Statistical Abstract : India (CSO) and Monthly Statistics of Foreign Trade of India (DGCI&S, Ministry of Commerce). For computing import-availability ratio at constant prices, the series on domestic production has been deflated by the wholesale price index of machinery and transport equipment, and the series on exports and imports have been deflated by the corresponding unit value indices.

It is interesting to note from Table 4 that the import-availability ratio at current prices does not show any significant upward or downward trend in the period 1975-76 to 1985-86. The ratio remains in the range of 14 to 18 per cent. Between the two end points, the ratio increases marginally from 17.04 per cent to 17.76 per cent. In the study of Chandrasekhar (1987), on the other hand, a significant increase was found in the import-availability ratio, from 20.96 per cent in 1976-77 to 26.65 per cent in 1983-84. The difference in the results of the two studies in regard to the trend in import-availability ratio is primarily attributable to the data sources used for domestic production of capital goods. Chandrasekhar has used production data of DGTD (Directorate General of Technical Development) while we have used production data of ASI. The coverage of DGTD is smaller than that of ASI, with the result that production figures reported by DGTD are much lower than those reported in ASI. A comparison of output figures obtained from the two sources is presented below:

	Value of Production in 1983-83 (Rs. Crore)	
	DGTD	ASI
Non-Electrical machinery	3197	5346
Electrical machinery	2644	4725
Transport equipment	2277	5007
Total	8118	15078

The output figures reported in ASI, we feel, represent more correctly the level of domestic production activity than the figures reported by DGTD, and therefore the import-availability ratios computed using ASI data are more reliable.

Import-availability ratio at constant prices shows a pattern very similar to that observed for the ratio of real imports of capital goods to real gross domestic fixed capital formation in machinery and equipment, analysed earlier. A downward trend is seen in the import-availability ratio for the years 1975-76 to 1979-80, and a reversal of trend occurs in the early 1980s. A peak is reached in 1983-84, and then the import-availability ratio starts declining.

The two main points emerging from the above analysis are as follows:

- (i) Chandrasekhar (1987) and Singh and Ghosh (1988) have found a significant increase in import-availability ratio (at current prices) of capital goods from the mid-1970s. Similar computations made by us do not show any such clear upward trend. This difference in findings is traceable mainly to the sources of data used for domestic production. Chandrasekhar, and Singh and Ghosh⁶ have used output data of DGTD, while we have used ASI data (which we believe represents more correctly the level of domestic production activity).
- (ii) Our analysis based on import-availability ratio at constant prices, and the ratio of real imports of capital goods to real gross domestic fixed capital formation in machinery and equipment indicates that dependence on imports continued to decline beyond the mid-1970s, and it is only in the early 1980s that the dependence on imports began to rise. But, this upward trend did not sustain beyond 1983-84.

Changes in Tariff Rate

Table 5 shows, for different years from 1968-69 to 1988-89, the average realised (or effective) tariff rate on imports of machinery and transport equipment.⁷ A graphic presentation is made in Chart 2. To compute the tariff rate, we have divided customs duty collections on imports of machinery and equipment by the c.i.f. value of imports. Although the average realised tariff rate is affected by changes in the product composition of imports, an analysis of its trend is useful for judging how the overall structure of customs duties have changed over time.

From Table 5, it is seen that there was an appreciable and more or less steady increase in the average realised tariff rate on imported capital goods in the late 1960s, in the 1970s and in the early 1980s. The average tariff rate was 20.9 per cent in 1968-69. It increased to 26.1 per cent in 1970-71, 45.2 per cent in 1976-77, 61.8 per cent in 1981-82, and further to 75.1 per cent in 1984-85. It would appear therefore that the advantage to foreign producers provided by the liberalisation of import policy for capital goods was partly offset by the hikes in the effective tariff rate.

After 1984-85, there was a fall in the average realised tariff rate. It fell from 75.1 per cent in 1984-85 to 61.0 per cent in 1985-86, and 59.8 per cent in 1986-87. The tariff rates in 1987-88 and 1988-89 were 65.2 and 62.8 per cent which were marginally higher than the rate in 1986-87, but lower than the rate in 1984-85.⁸

In the computations of average realised tariff rate presented in Table 5, machinery has been combined with transport equipment. Tariff rates on imports of machinery are shown separately in Table 6. It is seen from the table that the tariff rate on machinery imports increased from 20.3 per cent in 1968-69 to 77.5 per cent in 1982-83 and 77.6 per cent in 1984-85. The tariff rate fell to 61.8 per cent in 1985-86 and 61.5 per cent in 1986-87. It was marginally higher in the next two years, but lower than the rate prevailing in 1984-85.

It will not be out of place to give here a brief account of important changes made in import duties in the last few years. In the Budget for 1985-86, the rate of import duty (basic plus auxiliary) on general projects was reduced from 65 per cent to 45 per cent. For power projects and fertilizer projects, the rate of import duty was brought down to 25 per cent and zero per cent respectively. Significant reduction in import duties (from 81.5 to 35 per cent) were also made for specified machinery for leather and leather products industry. For the benefit of the computer industry, import duty was reduced from 75 to 25 per cent for four important components of computers. Also, advanced computers were exempted from customs duty. The observed reduction in the average realised tariff rate in 1985-86 reflects in part these changes in tariff rates.

In 1986-87, the general machinery import duty rate was raised by 10 per cent. Similarly, the import duty rate on general projects was raised from 45 to 55 per cent. But, the duty rate on components was reduced by 5 per cent (to raise effective protection to domestic manufacture of capital goods). For 32 items of machine tools in which domestic production was established the duty rate was raised to 110 per cent, while for 91 items of machine tools in which there was negligible domestic production the rate of duty was reduced to 55 per cent.

In 1987-88, the rate of import duty on general projects was raised significantly from 55 to 85 per cent (i.e. to a level higher than that prevailing in 1984-85). On fertilizer projects, the import duty rate was raised from nil to 15 per cent and on electronics projects from 25 to 30 per cent. For power projects up to 50 MW capacity the duty rate was raised from 25 to 35 per cent. On the other hand, the general machinery rate of import duty was reduced from 101 per cent to 85 per cent. Thus, the general machinery and general project rates of import duty were equalised (to encourage modernisation of existing plants). Duty concessions on specified machinery were made for foundries and caustic soda plants based on mercury-cell. Also, import duty on special steel (an important material for machine manufacture) was reduced to 85 per cent to help domestic capital goods producers.

In 1988-89, duty concessions on specified machinery were made for several industries, including food processing, electronics, manufacture of watches, and roller bearing. For computer industry, the rates of import duty on different items were made more uniform.

In the Budget for 1989-90, the general machinery and general project rate of import duty was reduced from 90 to 80 per cent. The rates of import duty on components were also reduced by 10 per cent. Import duty on electronics projects was raised by 10 per cent, while that on power projects was raised by 5 per cent. In a large number of specified capital goods and components, concessional duty rates were prevailing in 1988-89. These rates were revised upward significantly. As a result of these changes, there was a reduction in the extent of variation in the rates of import duty on different capital goods.

To summarize, import duties were reduced significantly in 1985-86. In subsequent years, import duties were lowered for some items of machinery and equipment but raised for some others. Therefore, the average rate probably did not change much in these years.

Import Function for Capital Goods

Imports of capital goods depend on the tariff rate on capital goods, and also on the prices of capital goods prevailing in domestic and international markets, the exchange rate and the investment rate in the economy. To study the influence of all these factors on imports of capital goods (machinery and transport equipment) in India, we have estimated an import function, using time-series data for the period 1968-69 to 1986-87.

For estimating the import function the following specification has been used:

$$\ln M = a + b_1 \ln I + b_2 \ln RP + b_3 D + b_4 t + u$$

where M is the quantity index of capital goods imports, I is the rate of investment (real) in machinery and equipment in the economy, RP is the price ratio (tariff adjusted) of imported to domestic capital goods, and u is the random error term. D is a dummy variable, taking value unity for years 1977-78 to 1986-87 and zero for years 1968-69 to 1976-77. It is included in the equation to capture the effect of the liberalisation of import policy for capital goods which took place in the period after the mid-1970s. A trend variable t is included in the equation to pick up the influences of excluded variables (to the extent possible).

The relative price variable RP is defined as:

$$RP = p_w (1+r) / p_d$$

where p_w is the price index of imported capital goods, p_d is the price index of domestic capital goods and r is the tariff rate. Clearly, p_w depends on the price prevailing in international markets and the exchange rate(s).

The data sources used for the estimation of the import function may be mentioned briefly. The quantity index of imports of capital goods (machinery and transport equipment, RITC 7) and the corresponding price (unit value) index have been taken from Statistical Abstract, India (CSO) and Monthly Abstract of Statistics (CSO). For the domestic price variable, we have used the wholesale price index for machinery and transport equipment, taken from Index Number of Wholesale Prices in India (Office of the Economic Advisor, Ministry of Industry). Series on real gross domestic fixed capital formation in machinery and equipment has been taken from National Accounts Statistics (CSO). For variable r , we use the average realised tariff rate on machinery and transport equipment⁹, computed by us and shown in Table 4.

The estimated import function is shown below (t-values are in parentheses):

$$\ln M = -7.94 + 2.842 \ln I - 0.994 \ln RP + 0.118 D - 0.138 t$$

(4.30) (-6.69) (1.07) (-2.62)

$$n = 19 \quad R^2 = 0.957 \quad F = 78.3 \quad DW = 1.34$$

The coefficients of the investment variable I and the relative price variable RP are correctly signed and statistically significant at one per cent level. The value of R^2 for the equation is 0.957, which indicates that the estimated model gives a good fit to the data. However, it is seen that the coefficient of the dummy variable is statistically insignificant (though it has the expected positive sign). Thus, the regression results do not lend empirical support to the view that, in the period after 1976-77, liberalisation of import policy for capital goods caused significant increases in capital goods imports.

Our finding of a statistically insignificant coefficient for the dummy variable raises doubts about the appropriateness of taking 1977-78 as the year from which the effects of import policy liberalisation began to be felt significantly. It would be recalled in this connection that a downward trend in the ratio of capital goods imports to gross domestic capital formation in machinery and equipment, observed from the period 1968-69 to 1975-76, continued beyond the mid-1970s, and a reversal of trend occurred only in 1980-81. Further, a study of the import policy documents for different years of the 1970s, brings out that while some changes in import policy were initiated from the mid-1970s, more important changes were made in the late 1970s, the effects of which might have been felt from 1980-81 onwards. These considerations have led us to re-estimate the equation, replacing the dummy variable D by another one D*, which takes value zero for years 1968-69 to 1979-80 and one for subsequent years. The results are found to be better¹⁰, and it is this equation that we use for further interpretation and analysis. The estimated equation is shown below (t-values are in parentheses):

$$\ln M = - 6.56 + 2.764 \ln I - 0.655 \ln RP + 0.318 D^* - 0.150 t$$

(5.01) (-3.73) (2.63) (-3.43)

$$n = 19 \quad R^2 = 0.969 \quad F = 109.4 \quad DW = 2.00$$

In the re-estimated regression equation, the coefficient of the dummy variable D^* is positive and statistically significant at five per cent level. Thus, some empirical support is found for the hypothesis that a more liberal import policy resulted in higher imports of capital goods in the 1980s. Turning to other coefficients, it is seen that the coefficients of the investment variable I and the relative price variable RP are both statistically significant at one per cent level. The signs of the two coefficients are correct, and the numerical values plausible. Our results suggest a less than unitary price elasticity of import demand for capital goods. As the coefficient of the investment variable is well above one, it may be inferred that an increase in the investment rate in the economy tends to raise imports of capital goods more than proportionately. Since the function has been estimated from time-series data and a trend variable has been included, the estimated coefficient of I probably reflects the short-term impact. Clearly, in the short run, such a relationship between domestic investment activity and imports of machinery and equipment is not implausible.

The coefficient of the trend variable is negative, and statistically significant at one per cent level. As mentioned earlier, this variable is included in the equation to pick up the influences of excluded variables. It would be realised that the process of learning by doing, inflow of foreign technology (and investment), acquiring of technological capabilities, and creation of manufacturing facilities for sophisticated equipment in the country must have had a significant depressing effect on our capital goods imports. The finding of a negative coefficient for the trend variable probably reflects these influences.

The value of R^2 for the regression equation is 0.969, which indicates that the estimated model gives a good fit to the data. This is also borne out by Chart 3 in which actual and estimated values of the dependent variable are shown. It should be noted further that the estimated import function predicts the turning points quite well.

The analysis presented above indicates that there was a significant upward shift of the import function in the 1980s. To test for shifts of the function, dummy variables were used. The CUSUM test¹¹ provides an alternative method for detecting departures from constancy of regression relationships over time. We have also applied this test to study the stability of the estimated import function. The plot of the recursive residuals (on which the CUSUM test is based) is given in Chart 4. The plot indicates a structural break in the import function around 1980. This corroborates our finding based on the dummy variable method.

Performance of Engineering Companies

To supplement the analysis presented thus far, we examine next the performance of 25 selected engineering companies (15 general engineering and 10 electrical engineering companies) over the period 1970 to 1988. Two ratios are considered for the analysis, namely (i) rate of return on capital employed, and (ii) turnover ratio (net sales to total assets). The data are drawn from the Official Stock Exchange Directory, Bombay. The companies chosen for the analysis are such that the two ratios are available from the data source for most years of the period under analysis. In making the choice we have also taken into account the production structure of different companies so that we get a sample of companies well-diversified in terms of goods produced.

Tables 7 and 8 present the two ratios for the selected companies for the years 1970 to 1988. Simple averages for general and electrical engineering companies are also shown in the table. As seen from the table, generally the selected engineering companies did not experience any decline in the rate of

return on capital employed or the turnover ratio after the mid-1970s or even after the mid-1980s. The average ratios do not show any marked downward trend.

To test statistically whether there was a significant downward trend in the two ratios, trend lines have been fitted by OLS for each company separately. A significant negative coefficient of the trend variable is found in one case out of 25 for the rate of return on capital employed and in 4 cases out of 25 for the turnover ratio.

We have carried out a similar exercise for a larger number of companies, 30 general engineering and 20 electrical engineering, for a shorter period 1979 to 1986. It would be recollected that during this period there was a rapid growth of capital goods imports in India and the ratio of imported capital goods to gross domestic capital formation in machinery and equipment nearly doubled. Rate of return on capital and turnover ratio for the 50 sample companies for different years from 1979 to 1986 are shown in Tables 9 and 10. The average ratios shown in the table for general and electrical engineering groups do not exhibit any sharp decline over the period. Also looking at the performance of individual companies, a significant downward trend in the ratios is observed in only a small proportion of cases.

It may be concluded on the basis of these results that most of the sample companies have not been affected much by the liberalisation of import policy for capital goods. But, from this analysis, no general inference can be drawn about the effect of import liberalisation of capital goods on the domestic industry, because our sample, being based on Bombay Stock Exchange Official Directory, includes only private sector companies (some of which may be subsidiaries of foreign capital goods manufacturing companies and thus gaining from greater import penetration), while public sector units account for a major share of finished capital goods production in the country. It is therefore necessary to take a look also at the performance of public sector engineering units.

For 17 public sector enterprises manufacturing capital goods, Table 11 shows gross sales, capital employed, the ratio of gross profit to capital employed and the ratio of gross sales to capital in the years 1975-76 through 1988-89. It is seen from the table that many of these enterprises experienced a rapid growth in sales. What is more important to note from the table is that there did not occur in general a significant deterioration in the ratio of gross profits to capital employed (profitability ratio) and the ratio of gross sales to capital employed (turnover ratio). Thus, the liberalisation of import policy for capital goods does not seem to have seriously affected the performance of public sector engineering units selected for the study.

Table 12 shows the rates of return on invested capital earned by the non-electrical and electrical machinery industries during the period 1978-79 to 1985-86, based on factory sector results of ASI. It is interesting to note that there is no significant downward trend in the rate of return, rather there is a mild upward trend. Thus, even at the aggregate level, we do not find any significant adverse effect of import liberalisation on the profitability performance of the machine-building industry.

Concluding Remarks

The import policy for capital goods has been increasingly liberalised since the mid-1970s. The analysis presented in this paper indicates that a significant effect of the import policy liberalisation on imports of capital goods occurred only in the early 1980s. As regards the recent changes in import policy for capital goods, it seems that these did not contribute much to increases in capital goods imports. Our analysis reveals that a large part of the recent increases in capital goods imports is attributable to the depreciation of the Indian Rupee vis-a-vis foreign currencies. Although our dependence on imported capital goods increased sharply between 1979-80 and 1983-84, there has been a downward trend in this ratio in the years after 1983-84.

One aspect which received particular attention in the study is the effect of import liberalisation on financial performance of Indian capital goods manufacturers. Our analysis brings us to the conclusion the domestic capital goods industry taken as a whole was not seriously affected by the liberalisation of import policy (though for certain types of capital goods demand problems might have arisen due to increases in imports); at least the effect was not as alarming as is often made out.

The average tariff rate on capital goods has more or less steadily increased since the late 1960s. Though there has been some decline after 1984-85, the average tariff rate in recent years has been much higher than the rates prevailing in the late 1960s and the early 1970s.

The tariff rate on capital goods in India is quite high in comparison with the rates obtaining in many other developing countries (see Table 13). At present the general machinery and general project rate of import duty is 80 per cent (though the average rate of import duty (basic plus auxiliary) for all capital goods imports is in the range of 40 to 50 per cent). Thus, even before a newly established factory based on imported machinery and equipment starts working, an Indian entrepreneur has much higher capital cost than his counterparts in other developing countries. That his products will be high cost and his competitiveness in international markets low, is therefore not surprising.

On this ground, a case can be made out for reducing import duties on capital goods, but one must also ensure that the domestic manufactures receive adequate protection (especially for those product lines in which domestic production is socially much more beneficial than imports). It is remarkable that despite high import duties on capital goods, the effective rates of protection have been found in studies to be low or negative for several items of capital goods. This is obviously due to high tariff on raw materials, components and parts used in the manufacture of capital goods. Evidently, by proper structuring of customs duties, it should be possible to have both lower import duty on machinery and adequate protection to domestic producers.

TABLE 1

Imports of Machinery and Transport Equipment in the 1980s

Year	Value of imports		Rate of change over the previous year (%)	
	(Rs crore)	(US \$ million)	based on (2)	based on (3)
1980-81	1821	2303	-	-

NOTES

1. Imports of OGL group III is dominated by one RITC category at 7-digit level, namely, 728.4809. This category includes 136 OGL items. Imports under this category in 1986-87 was Rs.1362 crores. Taking 10 per cent of this figure as import under OGL, the average value of imports of OGL items belonging to 728.4809 turns out to be about Rs. one crore.
2. In Table 1 and in the analysis presented later in the paper, a narrow definition of capital goods is used to cover only machinery and equipment (RITC 7). A broader definition is used for computing the relative share of capital goods under OGL, because a large number of items in the OGL list for capital goods belong to RITC codes 87 and 88.
3. It should be realised further that the entire increase in imports of these 201 items between 1984-85 and 1986-87 cannot be attributed solely to their being placed under OGL.
4. Deficiencies of unit value indices are well known. However, no better price index is readily available to deflate the imports value series.
5. The investment series has been taken from National Accounts Statistics, CSO.
6. Singh and Ghosh (1988) have presented two sets of import-availability ratios - for one set they use ASI data and for the other they use DGTD data. However, they base their conclusions about trends in import penetration on the second set of ratios, i.e. the ones computed from DGTD data. The import-availability ratios computed by them from ASI data do not show any significant rising trend, as in the ratios computed by us in the present study.
7. Tariff rates shown in the table include basic, auxiliary and additional duties. Imports of project goods and duties on them are included.
8. From the available estimates of capital goods imports and customs revenue collection for 1989-90, the average realised tariff rate turns out to be above 65 per cent.
9. It should be noted that the domestic wholesale price index for machinery includes excise duty, the unit value of imported machinery does not include customs duty, and the average realised tariff rate includes basic, auxiliary and additional (equal to excise) customs duties.
10. The value of R^2 is higher. All the coefficients are statistically significant. Also, there is an improvement in DW-statistic.
11. For details of CUSUM test, see Brown, Durbin and Evans (1975).
